

Answer

Dhruv Parashar - EE22BTECH11019*

Question: In a locality 'A', the probability of a convective storm event is 0.7 with a density function,

$$f_{X_1}(x_1) = e^{-x_1}, \quad x_1 > 0 \quad (1)$$

The probability of tropical cyclone-induced storm in the same location is given by the density function,

$$f_{X_2}(x_2) = 2e^{-2x_2}, \quad x_2 > 0 \quad (2)$$

The probability of occurring more than 1 unit of storm event is

Solution:

Laplace Transform

Let X be a random variable such that

$$X = X_1 + X_2 \quad (3)$$

Given,

$$f_{X_1}(x) = e^{-x}u(x) \quad (4)$$

$$f_{X_2}(x) = 2e^{-2x}u(x) \quad (5)$$

Where, $u(x)$ is unit step function.

CDF of X_1 :

$$F_{X_1}(x) = \int_{-\infty}^x f_{X_1}(x) dx \quad (6)$$

$$= \int_0^x e^{-x} dx \quad (7)$$

$$= 1 - e^{-x} \quad (8)$$

CDF of X_2 :

$$F_{X_2}(x) = \int_{-\infty}^x f_{X_2}(x) dx \quad (9)$$

$$= \int_0^x 2e^{-2x} dx \quad (10)$$

$$= 1 - e^{-2x} \quad (11)$$

Now,

$$M_X(s) = M_{X_1}(s) \cdot M_{X_2}(s) \quad (12)$$

$$M_{X_1}(s) = \int_{-\infty}^{\infty} f_{X_1}(x) \cdot e^{-sx} dx \quad (13)$$

$$= \int_0^{\infty} e^{-x} \cdot e^{-sx} u(x) dx \quad (14)$$

$$= \frac{1}{s+1} \quad (15)$$

Region of Convergence(ROC) of $M_{X_1}(s)$:

$$Re(s) > -1 \quad (16)$$

Now,

$$M_{X_2}(s) = \int_{-\infty}^{\infty} f_{X_2}(x) \cdot e^{-sx} dx \quad (17)$$

$$= \int_0^{\infty} 2e^{-2x} \cdot e^{-sx} u(x) dx \quad (18)$$

$$= \frac{2}{s+2} \quad (19)$$

ROC of $M_{X_2}(s)$:

$$Re(s) > -2 \quad (20)$$

Using (15) and (19) in (12)

$$M_X(s) = \frac{1}{s+1} \times \frac{2}{s+2} \quad (21)$$

$$= \frac{2}{(s+1)(s+2)} \quad (22)$$

$$p_X(x) = L^{-1}[M_X(s)] \quad (23)$$

$$= L^{-1}\left[\frac{2}{(s+1)(s+2)}\right] \quad (24)$$

$$= 2L^{-1}\left[\frac{1}{s+1} - \frac{1}{s+2}\right] \quad (25)$$

ROC of laplace transform:

$$Re(s) > -1 \cap Re(s) > -2 \quad (26)$$

$$\implies Re(s) > -1 \quad (27)$$

So, now

$$p_X(x) = 2(e^{-x} - e^{-2x})u(x) \quad (28)$$

CDF of X :

$$F_X(x) = \int_{-\infty}^x p_X(x) dx \quad (29)$$

$$= 2 \int_{-\infty}^x (e^{-x} - e^{-2x})u(x) dx \quad (30)$$

But $p_X(x)$ is integrable for $x > 0$

$$F_X(x) = 2 \int_0^x (e^{-x} - e^{-2x}) dx \quad (31)$$

$$= 2 \left(-e^{-x} + \frac{1}{2} e^{-2x} \right) \Big|_0^x \quad (32)$$

$$= 2 \left(-e^{-x} + \frac{1}{2} e^{-2x} + \frac{1}{2} \right) \quad (33)$$

$$= -2e^{-x} + e^{-2x} + 1 \quad (34)$$

Now,

$$\Pr(X > 1) = F_X(1) \quad (35)$$

$$= -2e^{-1} + e^{-2} + 1 \quad (36)$$

$$= 0.39 \quad (37)$$

Steps for simulation the given distribution

1) CDF of X_1 is given as:

$$F_{X_1}(x) = \begin{cases} 0 & x \leq 0 \\ 1 - e^{-x} & x > 0 \end{cases} \quad (38)$$

2) Declare a function inverse cdf ($I(u)$) such that its input is any random number and output is random variable whose cdf equals that of the given distribution

For $x \leq 0$

$$u = 0 \quad (39)$$

$$\because x \leq 0 \quad (40)$$

$$u \leq 0 \quad (41)$$

For $x > 0$

$$u = 1 - e^{-x} \quad (42)$$

$$e^{-x} = 1 - u \quad (43)$$

$$x = -\ln(1 - u) \quad (44)$$

$$\because x > 0 \quad (45)$$

$$u > 0 \quad (46)$$

$$I(u) = \begin{cases} 0 & u \leq 0 \\ -\ln(1 - u) & u > 0 \end{cases} \quad (47)$$

3) Define three arrays `random_vars`, `cdf_values`, `theoretical_cdf_values` to store random variables, simulated cdf values and theoretical cdf values

4) Generate random numbers using `rand()` and calling inverse cdf function to generate our random variable

- 5) Calling cdf function to calculate the cdf of the generated random variable
- 6) Storing the random variable, theoretical cdf and generated cdf into their respective arrays
- 7) Storing the data of these three array into a .dat file
- 8) Plotting these .dat file in python
- 9) Repeat all these steps for X_2 as well as X
